

P — policy

failure exercised in 39 of 104

Ed25519 signature over the policy object; identity, version, window and digest gates.

Λ

E — evidence

failure exercised in 36 of 104

Ed25519 signature over the evidence object; nonce replay set.

Λ

S — runtime state

failure exercised in 17 of 104

Structural appraisal of a corpus-supplied attestation-result object (status, freshness window, reference digest). NOT cryptographic attestation.

Λ

A — delegated authority

failure exercised in 30 of 104

Typed 1/2/4-hop delegation-path evaluator over 16 cases; consumes corpus-supplied validity flags and verifies no signature.

Λ

M — measurement

failure exercised in 39 of 104

Profile digest, point estimate and one-sided bootstrap lower confidence bound.

Λ

B — subject binding (join condition)

decided the verdict in 8 of 104

Not a sixth artefact and not a sixth verifier: deterministic string agreement and interval containment over subject fields the five verifiers already read — required effect and required measurement profile (signed policy); effect, resource, issued_at (signed evidence); terminal narrowed grant and the intersection of the per-edge validity windows (delegation path); profile identifier (measurement fixture). Verifies no signature, takes no measurement, is not attestation of any runtime.

ALLOW iff P Λ E Λ S Λ A Λ M Λ B

Non-compensable: any failed predicate denies and no predicate can compensate for another. A DENY carries first_rejecting_gate in the fixed evaluation order policy → evidence → state → authority → measurement → binding; B is consulted only when all five artefact verifiers pass, so the 8 transactions it decided are denials with zero failing verifiers. Protocol validity is a separate prior gate (20/20 vectors valid in the delegation laboratory).

Solid boxes are the five artefact verifiers; the dashed box is the join condition over their subjects. Counts describe the designed 104-transaction corpus with author-written expected labels; they are not rates and do not estimate prevalence in any deployed system. State appraisal is structural, not cryptographic attestation; authority flags are corpus-supplied, not verified signatures; the binding stage compares corpus-supplied subject strings and is not attestation of any runtime.
